L46: Entry 8 of 33

File: PGPB

Oct 10, 2002

DOCUMENT-IDENTIFIER: US 20020145426 A1

TITLE: Support structure for open MRI apparatusAbstract Paragraph:

An open or split type MRI apparatus has two axially spaced magnet coil half sections separated and supported by a compact support structure. Only two diametrically opposed supports are needed to react the high axial and torsional loads produced or received by the MRI apparatus. One support is loaded under pure compression, and the other support is loaded under compression and tension.

Summary of Invention Paragraph:

[0001] The present invention relates in general to structural supports for magnetic resonance imaging (MRI) apparatus and relates in particular to an open MRI apparatus having axially-spaced pairs of magnet coils supported by a pair of diametrically opposed supports.

Summary of Invention Paragraph:

[0002] An MRI magnet is characterized as open when there is an accessible, room temperature, physical gap provided between a pair of superconducting magnet coils. An open MRI magnet is desirable as it improves patient comfort and accessibility as compared to closed MRI magnets which many patients consider uncomfortable and which limit patient access.

Summary of Invention Paragraph:

[0003] In order to provide the desired openness and create an open gap around a patient imaging region, a pair of magnet coil assemblies can be separated into two axially-spaced half sections. The half sections of the magnet produce high attractive magnetic forces which must be reacted with a structural support system that separates and supports the half sections and prevents the magnet coils from collapsing upon one another.

Summary of Invention Paragraph:

[0004] Typical axial forces for a 1.0 T MRI magnet are in the range of about 160,000 lbs. (711 KN). Prior MRI support structures reacted these axial forces by an arrangement of axial posts which interconnected the two magnet half sections. The numerous posts limited the openness of the magnet.

Summary of Invention Paragraph:

[0005] An MRI support structure must not only axially separate and axially support the two magnet half sections during operation of the MRI apparatus, the support structure should also provide circumferential support to accommodate torsional or twisting forces which may be applied to the half sections during, for example, shipping, installation, mobile and normal operation. Moreover, it is desirable to provide such a support system which resists the transmission of floor-induced vibrations from the surrounding building structure to the MRI apparatus.

Summary of Invention Paragraph:

[0006] Accordingly, a need exists for a robust support structure for an open MRI apparatus which reacts high axial loads produced during operation of the apparatus, without adversely affecting the openness of the gap defined between two MRI magnet

half sections.

Summary of Invention Paragraph:

[0007] A further need exists for such a structure which reacts tensile and compressive loads produced by a pair of MRI half sections as well as any torsional loads which may be applied to the half sections.

Summary of Invention Paragraph:

[0008] Another need exists for a support structure for an open MRI magnet assembly which resists the transmission of vibrations from the surrounding building floor.

Summary of Invention Paragraph:

[0010] A further object of the invention is the provision of such a support structure which uses only two dramatically opposed supports for connecting together two MRI half sections to provide a high degree of openness with a minimum of patient obstruction.

Summary of Invention Paragraph:

[0013] Still another object of the invention is the provision of such a support structure which has very high bending, shear and torsional natural frequencies so as to make the MRI apparatus more tolerant to floor induced vibrations.

Summary of Invention Paragraph:

[0014] These and other objects are met by the present invention which is directed to a support structure for interconnecting and supporting a pair of half magnet sections of an MRI apparatus. The support structure includes two axially-extending supports or columns located diametrically opposite one another on the outer circumferential periphery of a pair of MRI magnet coil half sections. The opposed supports have unequal structural configurations and different cross sections and accommodate different types of loading.

Summary of Invention Paragraph:

[0016] The larger support is radially offset to one side of the magnet assembly to enable the open magnet to maintain a high degree of openness and to improve patient comfort and accessibility. In order to provide for the flow of cryogenic fluid, such as liquid helium, between the two magnet half sections, at least the larger support includes a hollow fluid flow portion.

Summary of Invention Paragraph:

[0017] To further enhance the openness of the MRI system, the outer vacuum container can be formed with an inner and outer conical portion to further reduce encroachment of the structure into the region of the imaging gap.

Brief Description of Drawings Paragraph:

[0020] FIG. 1 is a schematic perspective view of a helium vessel of an MRI apparatus constructed in accordance with the present invention;

Brief Description of Drawings Paragraph:

[0021] FIG. 2A is an axial cross sectional view of an MRI apparatus constructed in accordance with the present invention taken along section line 2A-2A of the representative helium vessel of FIG. 1. FIG. 2A is sectioned through the top half of a pair of diametrically opposed supports and is a mirror image of the lower half of the helium representative vessel of FIG. 1.

Detail Description Paragraph:

[0044] By circumferentially offsetting the two radially outer posts 54 on opposite sides of the radially inner post 50, the three posts 50, 54, 54 of the second support 18 provide a support structure which also resists and reacts circumferential torsional and shear loads. Moreover, by locating the first and second supports diametrically opposite one another and radially outwardly from the

inner magnet coil portions 28, the support structure of the magnet half sections 12, 14 has very high bending, shear and torsional natural frequencies, which makes the MRI magnet assembly more tolerant to floor induced vibrations.

Detail Description Paragraph:

[0046] It should be noted that the largest electromagnetic forces occur on the main coil 34 and shield coil 36. For this reason, the magnet half sections 12, 14 are strongly reinforced in these areas. This strength is provided by a series of concentric cylindrical structural support members and a series of radially-extending circumferentially-spaced gusset plates as described below.

Detail Description Paragraph:

[0048] Additional rigidity is provided to each of the magnet half sections 12, 14 by a series of radially-extending circumferentially-spaced gusset plates 72. Plates 72 may be welded to the inner and outer flanges 66, 68 as well as to the inner cylinder 64. From 8 to 32 (or more) gussets plates 72 may be used to reinforce the magnet half sections 12, 14 via arrangement in a spoke-like array as seen in FIG. 8.

Detail Description Paragraph:

[0052] Both the helium vessel support posts 16, 50, 54 and the thermal shield posts 94, 96 are enclosed in the outer vacuum container posts 100, 102, as seen in FIG. 5A. The posts 100, 102 rigidly interconnect the two halves of the outer vacuum container 92 together. The upper half of the container 92 is shown in FIG. 7A and the lower half is shown in FIG. 7B. A top view of the outer vacuum container is shown in FIG. 11. Post 100 is cylindrical in shape and post 102 is six sided to compliment the six sided section of the thermal shield post 96.

CLAIMS:

1. An open MRI apparatus, comprising: a first magnet half section; a second magnet half section; and a support structure interconnecting and supporting said first and second magnet half sections, said support structure comprising a first support and a second support and wherein said first support is loaded under compression and said second support is loaded under compression and tension.

L46: Entry 32 of 33

File: USPT

Jul 19, 1988

DOCUMENT-IDENTIFIER: US 4758812 A

TITLE: Frame structure for a magnet system for nuclear spin tomography

Abstract Text (1):

A frame structure for supporting individual magnetic coils forming a magnet system used in nuclear spin tomography comprises several frame parts made from a ferromagnetic material to provide relatively simple magnetic shielding. The individual magnetic coils are concentrically aligned one behind the other along a common axis to form the magnet system. Several elongate beam, rod, or plate-shaped magnetic shielding elements extend parallel to the common axis and are evenly distributed in the circumferential direction around the magnet system thus forming a generally cylindrical surface. End-plate magnetic shielding parts having a central opening of predetermined radius are provided at the end faces of the cylindrical surface formed by the shielding elements to create a cage-like frame structure. Coil receiving elements can be used to rigidly connect the axis-parallel shielding elements with the individual magnetic coils.

Brief Summary Text (3):

Picture-producing methods have been developed in the field of medical diagnostics wherein by calculation or measurement, integral resonance signals of the nuclei of a given body element to be examined (particularly that of a human body) are analyzed. From the spatial spin density and/or the relaxation time distribution obtained in this manner, an image similar to that of X-ray tomography may then be constructed. Various techniques of this manner are well known under the designation "Nuclear Spin Tomography" (nuclear magnetic resonance tomography) or "Zeugmatography".

Brief Summary Text (5):

The base field magnet may be designed as a system of, for example, six individual ring-shaped magnetic coils which are lined up one behind the other along a common axis in the direction of the desired field orientation of the magnetic base field. A frame structure, such as the one disclosed in European Patent No. 0 102 486 A1 comprising several frame parts which extend parallel to the common axis is used for mounting and/or spatially adjusting the individual magnetic coils. In order for the desired high homogeneity of the magnetic field to be achieved, fine geometric adjustments must be made to at least one of the individual coils. European Patent No. 0 102 486 A1, mentioned above, discloses adjusting and holding means which are particularly well suited for this purpose.

Brief Summary Text (10):

According to the invention, these problems are solved by integrating into the frame structure elongate beam, rod, or plate-shaped magnetic shielding elements in connection with end-plate magnetic shielding parts. The beam, rod or plate-shaped elements represent the frame parts of the structure extending parallel to the common axis of the magnetic coils. In this manner a compact highly stable frame structure is assured wherein the frame structure performs the function of the magnetic shielding. Also the magnetic shielding frame structure allows easy access to the individual coils for fine adjustment.

Detailed Description Text (2):

Referring to FIG. 1, a first embodiment of a magnet system and frame structure used in nuclear spin resonance technology is shown. The magnet system designated generally at 2 is formed by several individual normal or superconducting coils 3-8 arranged concentrically with respect to the horizontal z-axis of an orthogonal xyz coordinate system. These coils provide a sufficiently homogeneous magnetic base field in a central imaging range, at the center of which M is located the origin of the xyz coordinate system. The magnet system 2 being cylindrical in shape allows for axial access to the homogeneous central imaging range through the end faces thereof. For example, a human body which is to be examined can be placed in the central field region along the z-axis.

Detailed Description Text (3):

The individual annular magnetic coils 3-8 of the magnet system 2 are concentrically lined up one behind the other along the z-axis and are held within a frame structure 10. Two of the magnetic coils, preferably the coils 4 and 7, located adjacent to magnetic coils 3 and 8, respectively, which are next to the end faces, are rigidly connected to the frame structure 10. The rigid connection is made by ring-shaped coil-receiving elements 12 and 13 made from a non-ferromagnetic material, for example, from a casting of an aluminum alloy. These ring-shaped elements lie in a plane perpendicular to the z-axis, i.e., in a radial plane. The remaining magnetic coils 3, 5, 6 and 8 are braced against at least one bottom part 16 through separate support devices 15 within the frame structure 10. In addition, these magnetic coils may be mutually aligned by means of special mechanical positioning devices 17 which are also attached to the frame structure 10. Examples of such support devices 15 and positioning device 17 can be seen from the above mentioned European Patent No. 0 102 486 A1.

Detailed Description Text (4):

The parts of the frame structure 10 extending parallel to the common z-axis are formed by several elongate beam, rod, or plate-shaped shielding elements 19 made from a ferromagnetic material. The arrangement of these elements 19 is shown in detail in FIGS. 2, 4 and 5. As is further shown from FIG. 1, end-plate shielding parts 21 and 22 made from a ferromagnetic material are attached to the end faces of the frame structure 10. Each end plate shielding part has a central opening 23 of a predetermined size. These shielding parts, also designated as pole irons, are required to enable sufficient shielding action. The end plates are rigidly connected to the elongate magnetic shielding elements 19, for example, by a screw connection. In this manner, a frame structure of sufficiently high mechanical stability consisting of the parts 12, 13, 19, 21 and 22 is assured.

Detailed Description Text (5):

The design of the frame structure 10 is shown more clearly from the cross sectional views of FIG. 2, taken partly in a plane through the magnetic coil 4 (left half of FIG. 2) and partly in a plane through the magnetic coil 3 (right half of FIG. 2). The ring-like coil receiving elements 12 and 13, of the frame structure 10 are identically designed. However, only element 12 is visible from FIG. 2. The ring-like coil receiving elements 12 and 13 may be composed of several segment-like individual pieces 12a to 12e made from a nonmagnetic material as shown in FIG. 2. These individual pieces may be bolted together to form the ring-like coil receiving elements 12, 13. In addition, the segment-like pieces 12a to 12e have several axial openings or feedthroughs 24 all of which have the same dimensions into which the elongate beam or rod-like magnetic shielding elements 19 may be inserted. A preferred location for the openings 24 and the elongate magnetic shielding elements 19 is chosen such that they lie on a common imaginary cylindrical surface about the z-axis surrounding the circumferential periphery of the magnet system. The openings 24 and elongate magnetic shielding elements 19 are evenly distributed around the z-axis as seen in the circumferential direction. The shape and operation of the elongate magnetic shielding elements 19 representing the parts of the frame structure 10 extending in the axial direction are known per se (see, European Pat. No. 0 141 149 A1).

Detailed Description Text (7):

A further embodiment of a frame structure 28 about a magnet system 2 is shown in FIGS. 3 and 4. The presentation of FIGS. 3 and 4 corresponds largely to the presentation given for FIGS. 1 and 2. The frame structure 28 differs essentially from the frame structure 10 of FIGS. 1 and 2 only in that it has no special coil receiving elements made from a non-magnetic material through which the magnetic coils 4 and 7 are utilized for additional stiffening of the frame structure. The frame structure 28 consists substantially of the ferromagnetic end plates 21 and 22 together with the axially extending elongate magnetic shielding elements, in this case of rod-like shape 29, to form a rigid unit. In this embodiment the frame structure 28 is formed by the cage-like shielding itself. This has the advantage that the entire frame structure surrounding the magnetic coil system can be independently moved and adjusted.

Detailed Description Text (8):

Further, it is shown in FIGS. 3 and 4 that the non-adjustable magnetic coils 4 and 7 are bolted to the bottom parts 16 through gusset plates 30 which engage the coils laterally.

Detailed Description Text (9):

FIG. 5 shows a cross sectional view through magnetic coil 5 of a further frame structure 40 about the magnetic system indicated in FIG. 1. The frame structure 40 is comparable to the frame structure 28 in that it is composed only of ferromagnetic shielding parts. Accordingly, frame structure 40 contains several elongate magnetic plate-shaped shielding elements 41 to 46 which longitudinally extend in the direction of the z-axis and are spaced at their adjacent longitudinal sides by small spaces 47. Thus the several shielding elements 41 to 46 form, for the most part a closed tubular shielding enclosure which is mechanically held together by means of ferromagnetic front plates which are not visible in the figure but may correspond, for example, to the end plates 21 and 22 according to FIG. 1. The individual magnetic coils can then be connected to the frame structure 40 through support elements 48 and 49 as well as holding and adjusting elements 50 to 52.

Detailed Description Text (10):

According to the embodiment shown in FIG. 5 the magnetic shielding element frame structure 40 has approximately a hexagonically interior cross section for receiving the individual magnetic coils of the magnet system. It goes without saying that other polygons may be formed by a corresponding number of elongate magnetic plate-shaped shielding elements without detracting from the invention.

Detailed Description Text (11):

According to the invention, a ferromagnetic return is co-integrated into a cage-like frame structure about a system of several ring-shaped magnetic coils. The mutually spaced ferromagnetic shielding elements which may have cross section dimensions other than those shown in the figures, represent the axial parts of the frame structure and are connected to each other by means of two ferromagnetic end plates on the end faces thereof. The frame structures of this invention are relatively easy to assemble in situ. Further, they ensure secure mounting of the individual ring-shaped magnetic coils while simultaneously allowing for fine adjustment.

CLAIMS:

1. In a frame structure with devices for supporting and for adjusting ring-shaped magnetic coils of a magnet system which are lined up one behind the other along a common axis, which magnet system generates a homogenous magnetic base field for an installation used in nuclear spin tomography, said frame structure including a plurality of frame parts extending parallel to the axis, the improvement

comprising:

(a) said frame parts extending parallel to the axis being elongate magnetic shielding elements disposed on an imaginary cylindrical surface surrounding the magnet system and distributed regularly in the circumferential direction forming a cage-like structure;

(b) said frame parts being mechanically connected with means for supporting and adjusting the ring-shaped magnetic coils of the magnet system within the frame structure;

(c) at least one ring-like coil receiving element made of a non-ferromagnetic material rigidly connecting the individual magnetic coils to the elongate magnetic shielding elements extending parallel to the axis; and

(d) a plate shaped magnetic shielding part with a central opening of predetermined radius at each of the end faces of said cage-like frame structure.

2. A frame structure according to claim 1 wherein said elongate magnetic shielding elements extending parallel to the axis in conjunction with said plate-shaped magnetic shielding parts at each of the end faces of said cage like structure alone form the frame structure.

5. A frame structure according to claim 1 wherein said elongate magnetic shielding elements are of a beam-shape.

6. A frame structure according to claim 1 wherein said elongate magnetic shielding elements are of a rod-shaped.

7. A frame structure according to claim 1 wherein said elongate magnetic shielding elements are of a plate-shape.

DOCUMENT-IDENTIFIER: US 4560933 A

TITLE: Apparatus for adjustably mounting coils of a magnet system for nuclear spin tomography

Brief Summary Text (5):

U.S. Pat. No. 4,315,216 discloses a magnet system for generating a base field, which system comprises four ring-shaped magnet coils which are aligned along a common horizontal axis. Since, as is well known, the homogeneity of the field of these coils must meet stringent requirements and should not vary, for instance, more than 0.01% of the magnetic field strength in the entire measuring volume, the positions and orientations of individual coils of the magnet system must be finely adjustable. Such adjustability is necessary even in cases of the highest manufacturing precision with respect to the magnet coils in order to compensate, for instance, the influence of iron parts in the vicinity of the magnet system. Each of the four magnet coils has maximally three degrees of freedom of translation and two degrees of freedom of rotation. Accordingly, a number of devices must be provided for mutually aligning the individual magnet coils. In this magnet system, all four adjustable magnet coils are supported on a common base plate. At one end face of each of the magnet coils are fastened four circumferentially equispaced plate-shaped elements which project radially outwardly. Corresponding plate-shaped elements of the four magnet coils are connected to each other via a common threaded rod. The axial positions and angular orientations of the individual coils within the frame structure are precisely determined by adjusting fastening nuts, by which plate-shaped elements of the coils are secured to the respective threaded rods. Furthermore, the individual magnet coils of the known magnet system can be aligned in the vertical direction via adjusting devices engaging the base plate (see FIGS. 4a and 4b of the above-identified patent). In this known magnet system, the expenditure for adjustment is relatively large since five adjusting devices are provided for each magnet coil. Furthermore, because the individual magnet coils are connected to each other via the threaded rods, thermal length changes and vibrations of these coils lead to a de-adjustment of the entire system and thus to a corresponding degradation of the homogeneity of the magnetic base field. Readjustment is relatively difficult in this case.

Brief Summary Text (11):

(c) that each support device contains a support element in the form of a spherical sector with a spherical surface rotatably inserted in a recess of the support device fixed with respect to the respective magnet coil and with a flat side slidably resting on horizontal support surface of the frame structure, and

Detailed Description Text (3):

The base field magnet array 2 comprises advantageously six annular magnet coils 6 to 11 which are aligned with each other along the z axis. Two of these magnet coils, preferably coils 7 and 10 which are adjacent to magnet coils 6 and 11 at the ends of array 2 are rigidly connected to a frame structure 45 which comprises two support bars 13 and 14 and a holding bar 15, as shown in FIG. 2. Support bars 13 and 14 rest on a substructure 17. Magnet coils 7 and 10 are held up via support devices 19 (not shown in detail) resting on the lower bars and are fixed to these

bars by metal sheets 20, so-called gusset plates. Gusset plates 20 engage magnet coils 7 and 10 laterally via tabs 21 and are bolted to support bars 13 and 14. Stationary magnet coils 7 and 10 are each rigidly connected to holding bar 15 via a claw-like fastening element 23. Support bars 13 and 14 as well as holding bar 15 thus form, together with the magnet coils 7 and 10, the rigid frame structure 45 in which the remaining magnet coils 6, 8, 9 and 11 are arranged adjustably by devices according to the present invention.

Detailed Description Text (5):

The support points A of the adjustable magnet coils 6, 8, 9 and 11 at support bars 13 and 14 as well as the tilting of these magnet coils with respect to the x-y plane due to mechanical couple K can be adjusted by setting or adjusting devices 27 and 28. Each positionable magnet coil 6, 8, 9 and 11 has two position setting devices 27 at support bars 13 and 14 and a third setting device 28 at holding or bracing bar 15. Setting devices 27 are juxtaposed to respective support devices 19 and are connected to a channel-shaped hollow profile body 29 which is open toward the bottom and which is fastened to the lower outside edge of the respective adjustable magnet coil, for instance, coil 11, in the vicinity of a support point. A support part or bracing projection 33 fastened to the support bar 13 (or 14) extends vertically into a space 32 within this hollow profiled body 29 between two free legs 30 and 31 thereof. The position of legs 30 and 31 of body or channel 29 and, therefore, of the magnet coil 11 relative to projection 33 is modifiable via an adjusting spindle 34 which extends substantially in the z direction and which is connected to outer leg 30, i.e., to the channel leg which is further away from the geometrical center M of magnet array 2, and is supported at one end by projection 33. Between this brace or projection 33 and the other free leg 31 of channel 29 a spring element 35 is clamped. This spring element 35 pushes the magnet coil, in the de-energized state of the magnet system, against adjusting spindle 34. Therefore, there is always a force-locking connection from each positionable magnet coil 6, 8, 9 and 11 via the two respective adjusting spindles 34 to the support bars 13 and 14.

Detailed Description Text (9):

FIG. 2 shows gusset plates 20 and fastening tabs 21 via which magnet coil 7 is rigidly connected to support bars 13 and 14. Magnet coil 7 is further fastened to holding bar 15 via claw-shaped fastening element 23. In the case of the adjustable magnet coils, the gusset plates and the fastening claws are eliminated, and fastening elements 23 are replaced by adjusting devices 28, by which the magnet coils can be tilted slightly.

CLAIMS:

1. In a nuclear spin tomography system having n adjustably positionable magnet coils aligned with each other along a common axis for generating a homogeneous magnetic base field, the tomography system including a mounting apparatus with a frame structure and mechanical adjusting devices secured to stationary parts of the frame structure for adjusting the translational and angular positions of the magnet coils with respect to the frame structure, the improvement comprising:

at least one additional magnet coil rigidly connected to the frame structure and aligned with the adjustably positionable magnet coils along the common axis, said adjustably positionable magnet coils each being connected to said frame structure

via three of the mechanical adjusting devices, said magnet coils forming an array having a geometrical center, each of said adjustably positionable magnet coils having a center of gravity defining a respective center of gravity plane oriented substantially parallel to the windings of the respective magnet coil and at least approximately perpendicularly to said common axis, and

support means included in the mounting apparatus for transmitting the weight of the n adjustably positionable magnet coils to said frame structure, said support means including at least n first support elements each rigidly attached to a respective adjustably positionable magnet coil and each being provided with a concave spherical surface defining a recess, said support means further including at least n second support elements each in the shape of a spherical sector having a planar surface slidably engaging a horizontal surface of said frame structure and a convex spherical surface slidably engaging the concave spherical surface of a respective first support element, the support elements associated with an adjustably positionable magnet coil defining at least one support point at which weight is transferred from the respective magnet coil to the frame structure, said support point being spaced from the center of gravity plane of the respective magnet coil on a side of such plane opposite said geometrical center, thereby giving rise to a mechanical couple operating on the respective magnet coil and tending to shift the top thereof towards said geometrical center.
